

Before random sampling: where are the timelines concentrated?

151,547 timelines | 379 relations | 1,141 properties scanned

Existing labels: median of positive consecutive START-to-START gaps; before overlap fix.

- place of detention
- member of sports team
- position held
- country
- head of government
- country of citizenship
- Other relations

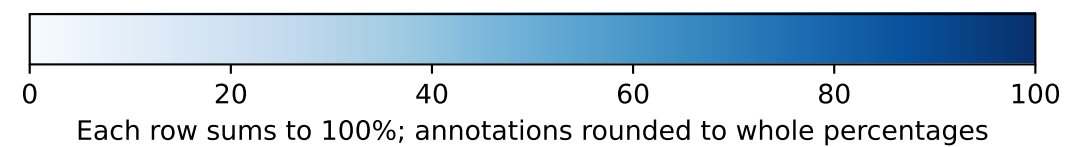

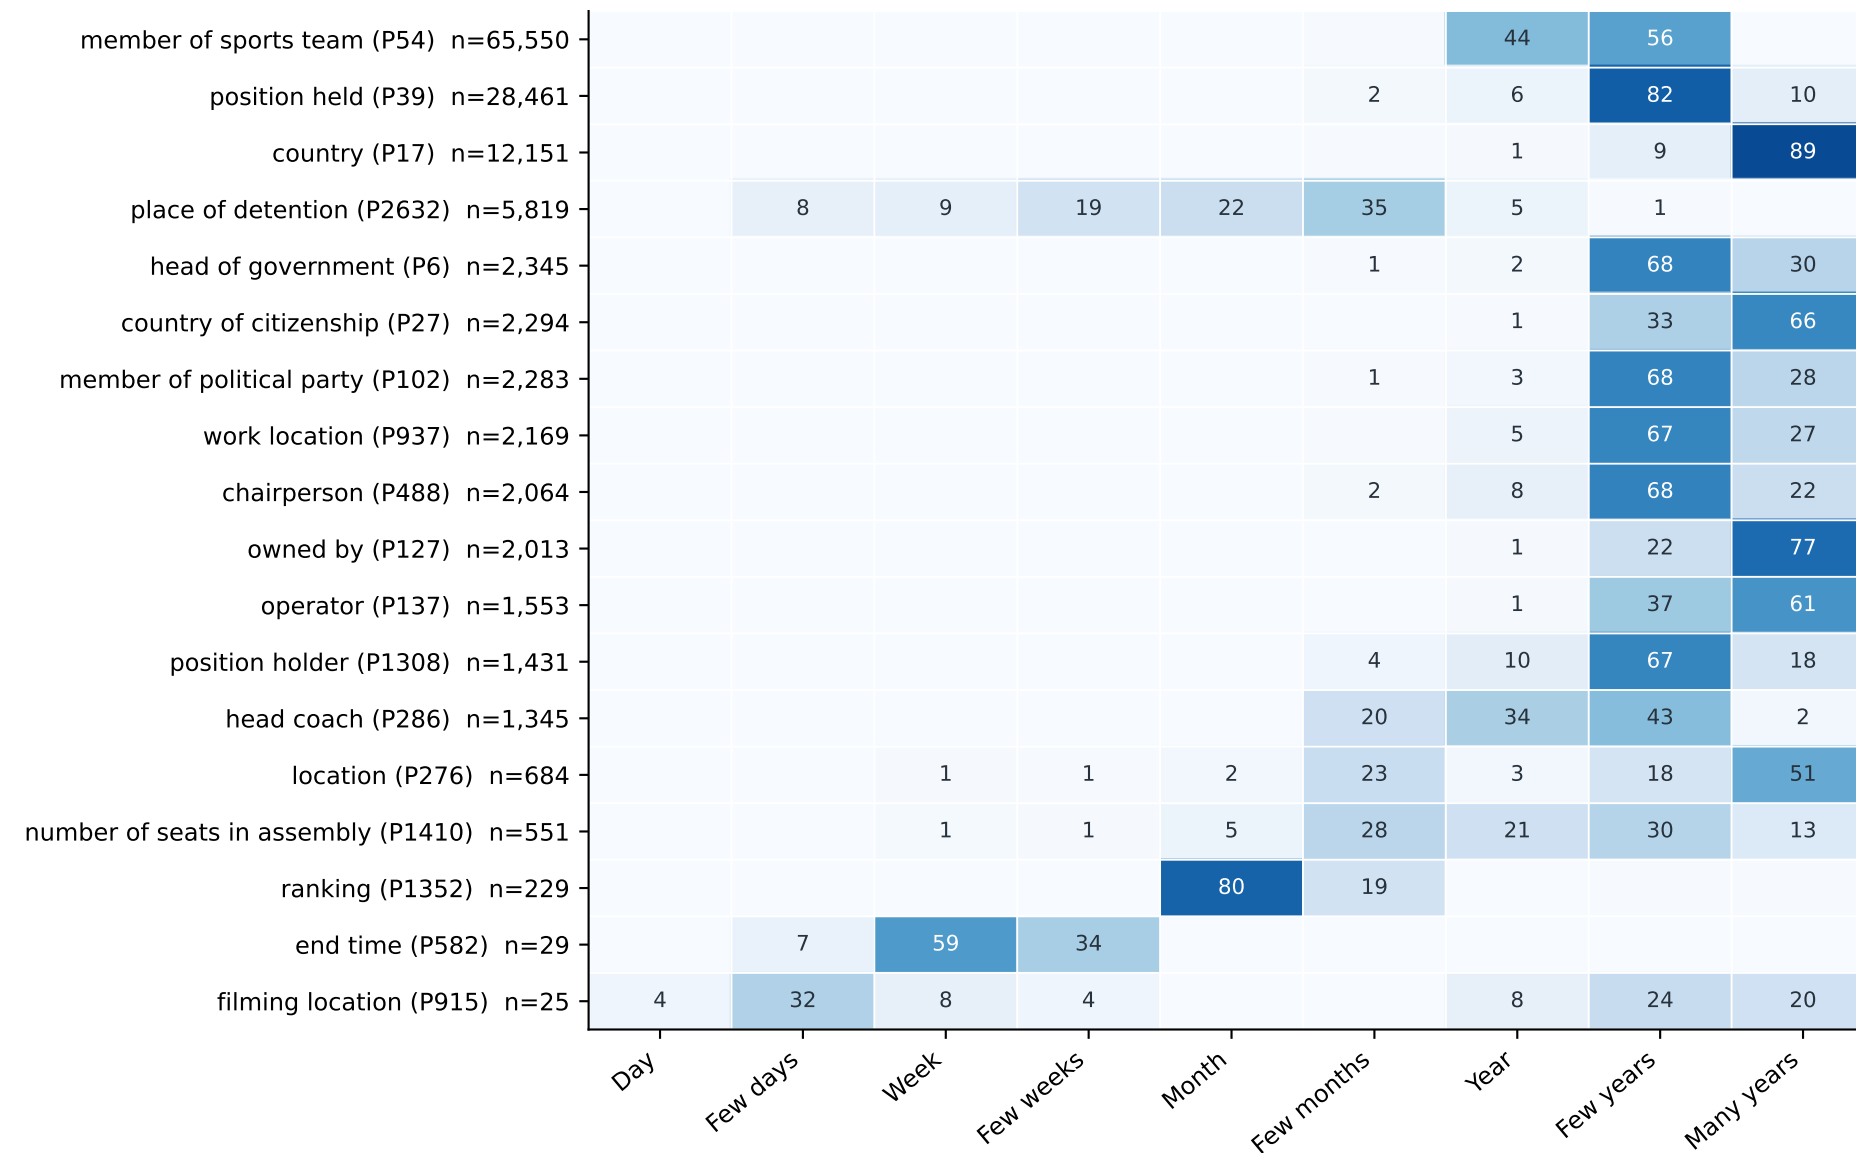

Each row in panel 2 sums to 100%. Day has only 20 timelines; its composition is based on very little data.

Relation and frequency: concentration versus enrichment

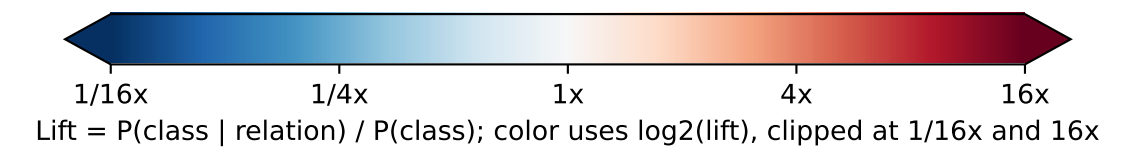

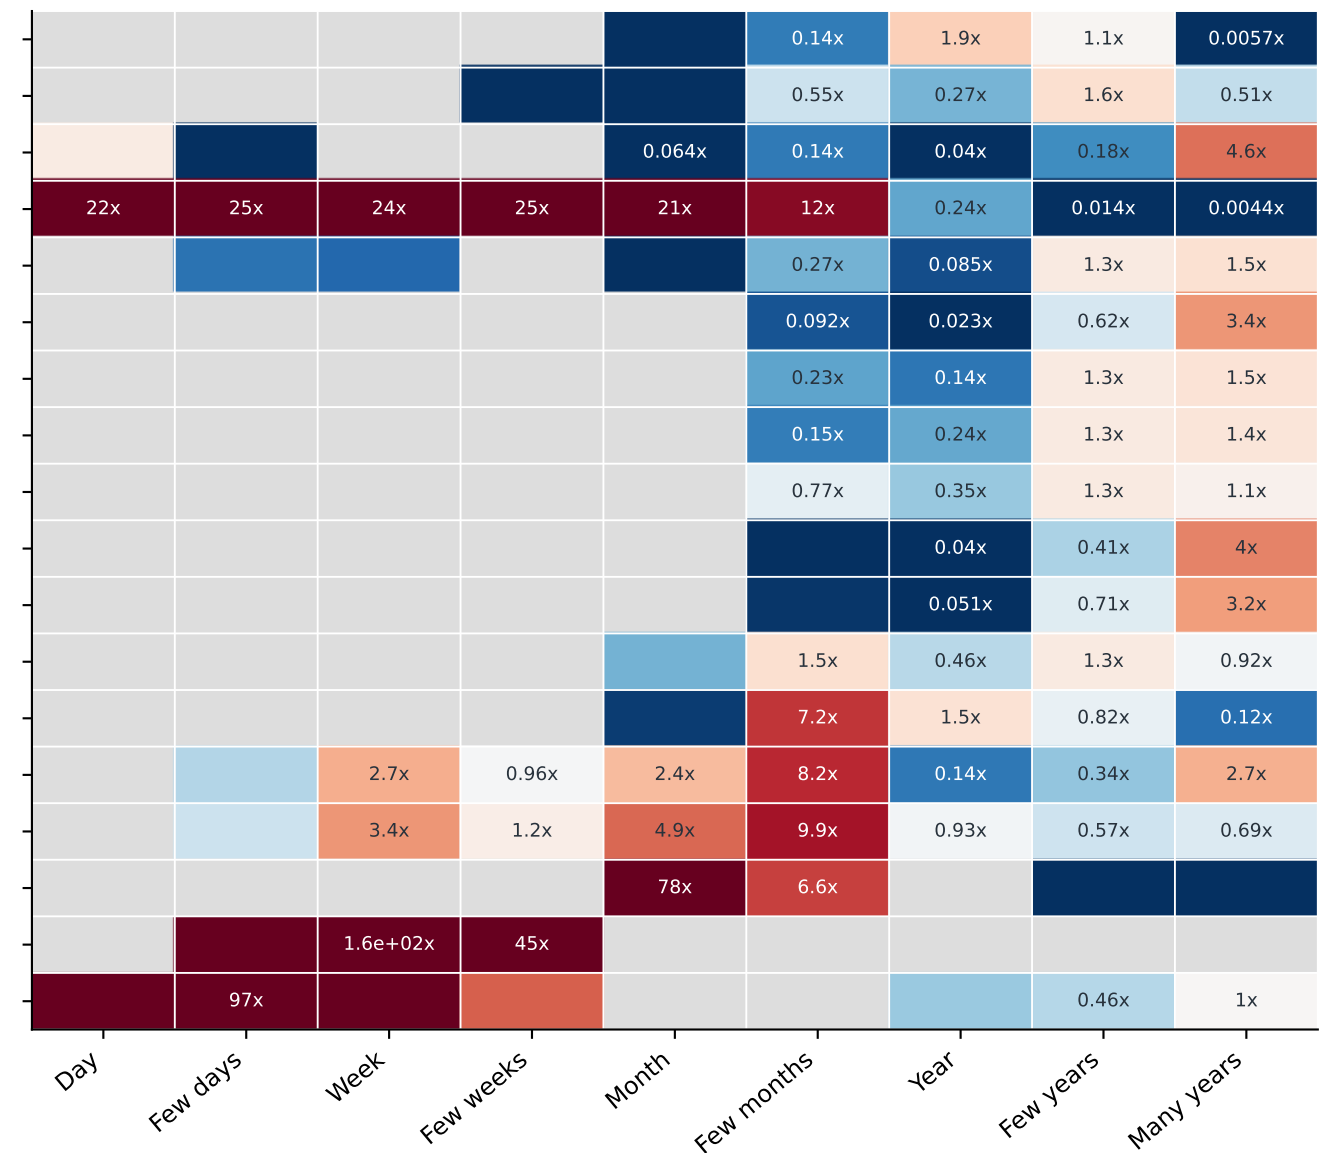

Cramer's $V = 0.446$ across all 379 relations (descriptive categorical association; not causation)

Existing labels: median of positive consecutive START-to-START gaps; before overlap fix.

3. Frequency distribution within each relation (%)

4. More or less common than the overall baseline?

Gray = zero observations. Lift annotations require count ≥ 5 ; sparse colored cells remain exploratory.
Rows: top 12 relations overall plus top 3 in each class with count ≥ 5 . Full 379-relation table is in the CSV.
